One workflow owns every consequential step.

Real recall evidence in. Human approval before action. Backend events prove what happened.

OFF is read back before remedy tracking begins.

Bedrock cannot set state, satisfy evidence, approve an action, or operate the device.

Live Bedrock inference still requires an authorized AWS profile, region, and model access.

Real evidence. Simulated hardware.

The boundary is explicit, and every consequential transition is visible.

REAL IN THIS DEMO

01 Live CPSC recall lookup

02 MCP Streamable HTTP server

03 **Deterministic workflow and approval gates**

04 Backend event feed and remedy tracking

05 Read-back of local device state

SIMULATED IN THIS DEMO

01 **Smart plug / device endpoint**

02 ON → OFF command and reported state

03 No physical hardware is connected

04 No claim is sent to a manufacturer

05 Bedrock explains only; never decides

A likely match is not proof. If evidence is missing, RecallGuard stands down.
